(Sysadmin)

The software package is available in source-code distribution. Since the project were written in C++ language and it is an object-oriented program, g++ (GNU C++ compiler) where used to compile the program. Released by the Free Software Foundation, g++ is a *nix-based C++ compiler usually operated via the command line. You can invoke g++ on a source code file simply by typing g++ filename. The default executable output of g++ is "`a.out`". It often comes distributed with a *nix installation, so if you are running a Unix or a Linux variant you likely have it on your system. If g++ was not installed on your system, you may find the file and instruction for installation here. Please notice that your g++ compiler should support the base standard library c++11.

1. Installation

There is a make file in the "`Solver`" folder. Write the following command in Unix/Linux command prompt window to build the executable "`a.out`" file:

```
make
```

and to run the program, run the following command:

```
./a.out
```

If you changed some part of the program and it may need to be recompiled, use the following command to first remove the old executable file and build the new one:

```
make clean
make
```
